Undergraduate Internship - Computer Engineering - Summer 2024

Intel,

I am writing to you in hopes of joining your team. I am very interested in the undergraduate computer engineering internship during the summer of 2024. I am extremely passionate about programming and learning more about any device that runs on 1's & 0's. Currently, I am learning my 7th programming language, C. I also have experience programming in Visual Basic Advanced, Python, MATLAB, AHK, Ti-Basic, and LC3 Assembly. I have always enjoyed problem solving and being challenged with puzzles to solve. Growing up in a rural area has helped push me to further develop my online research and design experimentation skills. Often, I had to figure things out on my own, because there was no where I could go for help or advice.

I converted my high school Chromebook into a Windows 11 computer. This project came with lots of challenges. My Chromebook was a Lenovo 500e. Most models have a physical Write-Protect screw within the motherboard to prevent the OS from being overwritten. Instead, the write protect feature for my model was built into the laptop's battery cable. It took a lot of research to discover this, and even more to figure out where to go from there. I disassembled the laptop many times during this process, which helped me develop important skills necessary for working with computer hardware safely. To flash Windows 11 to it, I had to disconnect the battery and plug the charger in as my power source. After the OS installation was complete and all the necessary Drivers (which also took a while to locate online) were installed, I was left with a touchscreen Windows 11 laptop. It now runs on battery power except when charging, just like any other Laptop.

I have 2 summers of experience as an engineering intern at Team Industries. Team Industries designs and produces CNC machined gears, pinions, and sprockets for many well-known customers including Polaris, Harley, and Boeing. During my time there, I learned a lot about the product development process. I had to create several spreadsheets using advanced formulas, conditional formatting, and even programming in Visual Basic Advanced. I also learned how to perform monotonous tasks such as inspecting thousands of gears very effectively by experimenting with different work flows to find what worked best for me. These gears had to be inspected because we found a large quantity of them were outside their allowed tolerances. We had to experiment and revise several aspects of our production process to determine the root cause. We found that the oil in one of our three heat-treat chambers, which we use to harden the machined parts, was old. This caused the parts to be inconsistently out of spec based on which chamber was used. This taught me a lot about problem solving in a professional environment.

Thank you for taking the time to consider me for the wonderful opportunity,

Connor Savugot
